Abstract: Trigonella foenum graecum (Fenugreek) was administered at 2 and 8 g/kg dose orally to normal and alloxan induced diabetic rats. It produced a significant fall \( P < 0.05 \) in blood glucose both in the normal as well as diabetic rats and the hypoglycemic effect was dose related.

Key words: rat Trigonella foenum graecum (Fenugreek) blood glucose alloxan induced diabetes

INTRODUCTION

Trigonella foenum graecum (Fenugreek) contains an alkaloid trigonelline and an essential oil. Its role as an antidiabetic has been described by Nadkarni (1). To produce hypoglycemic effect, Fenugreek seeds have been used as whole seed powder and cooked or roasted seed powder (1, 2, 3).

The present work was undertaken to study the effect of Fenugreek seeds on blood glucose levels in normal and alloxan induced diabetic rats.

METHODS

Thirty Wistar rats of either sex maintained on standard diet were administered unroasted Fenugreek seed powder mixed with the diet daily in a low dose of 2 g/kg and high dose of 8 g/kg body weight. In a preliminary study it was observed that roasted seeds had no effect on blood glucose levels in rats.

The animals were divided in two groups of fifteen rats each. Group A was further divided into 3 subgroups A1 to A3 consisting of 5 animals each.

Group B was made diabetic by a single intraperitoneal injection of alloxan monohydrate 5% w/v in normal saline in a dose of 120 mg/kg, b.w. Rats with blood glucose level higher than three times the normal after 3 days were included in the study. The diabetic rats thus selected were also divided into 3 subgroups (B1-B3) of 5 each. Rats in subgroups A1 and B1 served as control. Fenugreek seed powder was administered in a dose of 2 g/kg to groups A2 and B2 and 8 g/kg to groups A3 and B3.

After an overnight fast samples of blood were withdrawn through cardiac puncture under ketamine anaesthesia (50 mg/kg, im). The blood samples taken before, after 1 and 2 weeks of Fenugreek administration were estimated for glucose by Dubowski’s method (4). Statistical analysis was done using Student’s ‘t’ test.

RESULTS AND DISCUSSION

Blood glucose level decreased significantly both in normal and diabetic rats following unroasted Fenugreek seed powder administration (Table I). The hypoglycemic effect was more pronounced with higher dose. The percentage fall was 23.09% with high dose and 15.59% with the low dose in normal rats and 21.33% and 13.2% in diabetic rats respectively.

The hypoglycemic effect of Fenugreek has been shown in normal rats (5), and nondiabetic man (3).

Riyad et al (2) has not advocated its use in diabetes mellitus. However, their observations indicate a preventive role in the rats pretreated with Fenugreek before the induction of diabetes where they have shown reduction in the severity of onset of experimental diabetes and improvement in the diabetic status when followed by feeding of the same diet.

Fenugreek resembles guar gum in its high dietary fibre content and high viscosity (6). Its hypoglycemic effect is probably partly because of these factors. However, some other mechanisms might also be operative since viscosity does not appear to be responsible for the slow absorption and digestion of legume carbohydrates (7) and antidiabetic effect may be due to intestinal glucosidase inhibition (2).

Fenugreek seeds along with diet can have a modulatory role in the treatment of diabetes mellitus and can form a part of therapy in its management.
